

Figure 1: ThetaRad is the angular displacement x_{cm} is the linear displacement, Vel is the velocity

Topic: Page 1

Thinking through this logic will be important for understanding the rest of the lab. To fill in the missing pieces, think through the following questions.

Topic: Page 2

Figure 2: The Bang Bang controller is a way to use strict on / off states to get back to a threshold or target. All gas or no gas, there is no in between.

Changing the `delay()` would just get slower and slower response times and the controller would have a harder time doing what it needs.

Page 4: List online sources and collaborators.
no additional online sources outside of the lab links.
I had no help from other students.

Page 5: Self-evaluation:

- (a) What did you expect to learn? How to work with and use an encoder and what the different states of the quad meant.
- (b) Rate class participation and needed adjustments. I did pretty okay this week. Not my best, not my worst.
- (c) Grade yourself (0–4) and explain. I would give myself a 4. I did what I needed to.
- (d) What did you actually learn? I am having a better time with using the if else loops to work through different needed states. I also learned about the Motor Forward/backward stop library, that was pretty cool.
